Early syphilis	554	17.6	29	8.1	48	34.4	179	17.3	278	18.6
Under 20 yrs										
Chlamydia	2909	344.9	44	52.5	245	651.7	877	230.5	337	117.0
Gonorrhea	229	7.3	6	7.2	38	101.1	39	10.3	26	9.0
Early syphilis	10	1.2	1	1.2	0	0.0	5	1.3	4	1.4

Note: Rates calculated using 2012 SANDAG population estimates.

## Key Points comparing YTD cases reported through December 2011 to December 2012.

- Chlamydia has increased 7.1%.
  - Female (<17) chlamydia has decreased 28.3%.
  - Male rectal chlamydia has increased 14.3%.
- Gonorrhea has increased 19.9%.
  - Female (18-25) gonorrhea has increased 43.9%.
  - Female (≤17) gonorrhea has decreased 31.3%.
- Early syphilis has increased 22.0%.

Note: All data are provisional. Case count is based on the earliest of date of diagnosis, date of specimen collection and treatment date. Totals for past months might change because of delays in reporting from labs and providers.

## Editorial Note: Appropriate Screening and Presumptive Treatment for Individuals Exposed to Syphilis

Syphilis continues to be a major public health concern in San Diego County. Preliminary data indicate that reported early syphilis cases increased 22% in 2012 over 2011, with 554 cases in the county. The most infectious stages, primary and secondary, increased 14% to 329 cases in 2012.

Screening of individuals exposed to syphilis plays an important role in controlling the spread of disease. Individuals reporting a recent exposure to syphilis should be screened with both a non-treponemal (RPR, VDRL) and a treponemal (TPPA, FTA) syphilis test. The reactivity of a treponemal test in an individual with no previous history of syphilis will indicate an early infection. An individual with a previous history of syphilis infection will likely have a reactive treponemal test. In this case, a non-treponemal quantitative titer should be evaluated for a four-fold or two-dilution increase in titer indicating re-infection. For more information on these tests, please view the CDC webinar, Reverse Sequence Syphilis Screening.

Newly identified syphilis infections should be treated according to <u>established protocols</u>. Persons without serologic evidence of infection, but who were exposed within the 90 days preceding the diagnosis of primary, secondary or early latent syphilis in a sex partner, should be treated presumptively. Persons who were exposed >90 days before the diagnosis of primary, secondary or early latent syphilis in a sex partner should be treated presumptively if serologic test results are not available immediately and the opportunity for follow-up is uncertain. **Presumptive treatment options include benzathine penicillin G, 2.4 million units IM or doxycycline 100 mg bid x 14 days (if PCN allergic).** 

County of San Diego HIV, STD & Hepatitis Branch Health Advisors interview all early infectious syphilis cases to assure adequate treatment, and provide disease education and prevention messages. Most importantly, the advisors elicit a sexual contact history. All contacts are then notified of their potential exposure to syphilis and are advised to seek testing and presumptive treatment. Clients are referred to their primary care provider or offered services in the County of San Diego STD Clinics, which screen and presumptively treat individuals who have been exposed to syphilis.

For further information regarding appropriate screening and/or recommendations regarding presumptive treatment please call (619) 692-8501.

YTD: Year to Date

<sup>\*</sup>Includes confirmed and probable cases of neurosyphilis among cases of early syphilis only.

<sup>\*\*</sup>New infections are reported either as HIV or, if an individual was also diagnosed with AIDS within one month, as AIDS.

<sup>\*</sup>Includes cases denoted as "other" or "unknown" and for which no race/ethnicity data are specified
